How Does Stellar Gravity Affect Planets?

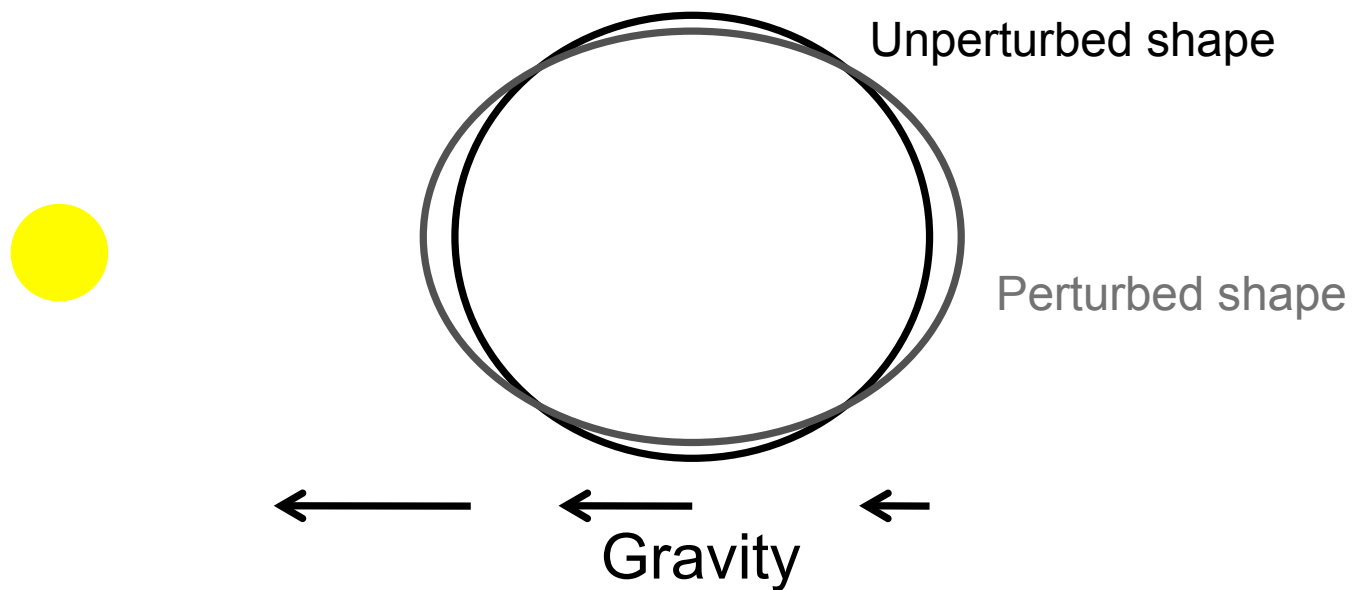

Rory Barnes

Tides

Close to a star, a planet feels a gravitational gradient

The planet resists, but it's shape is perturbed

An Orbit with No Tides

An Orbit with Tides

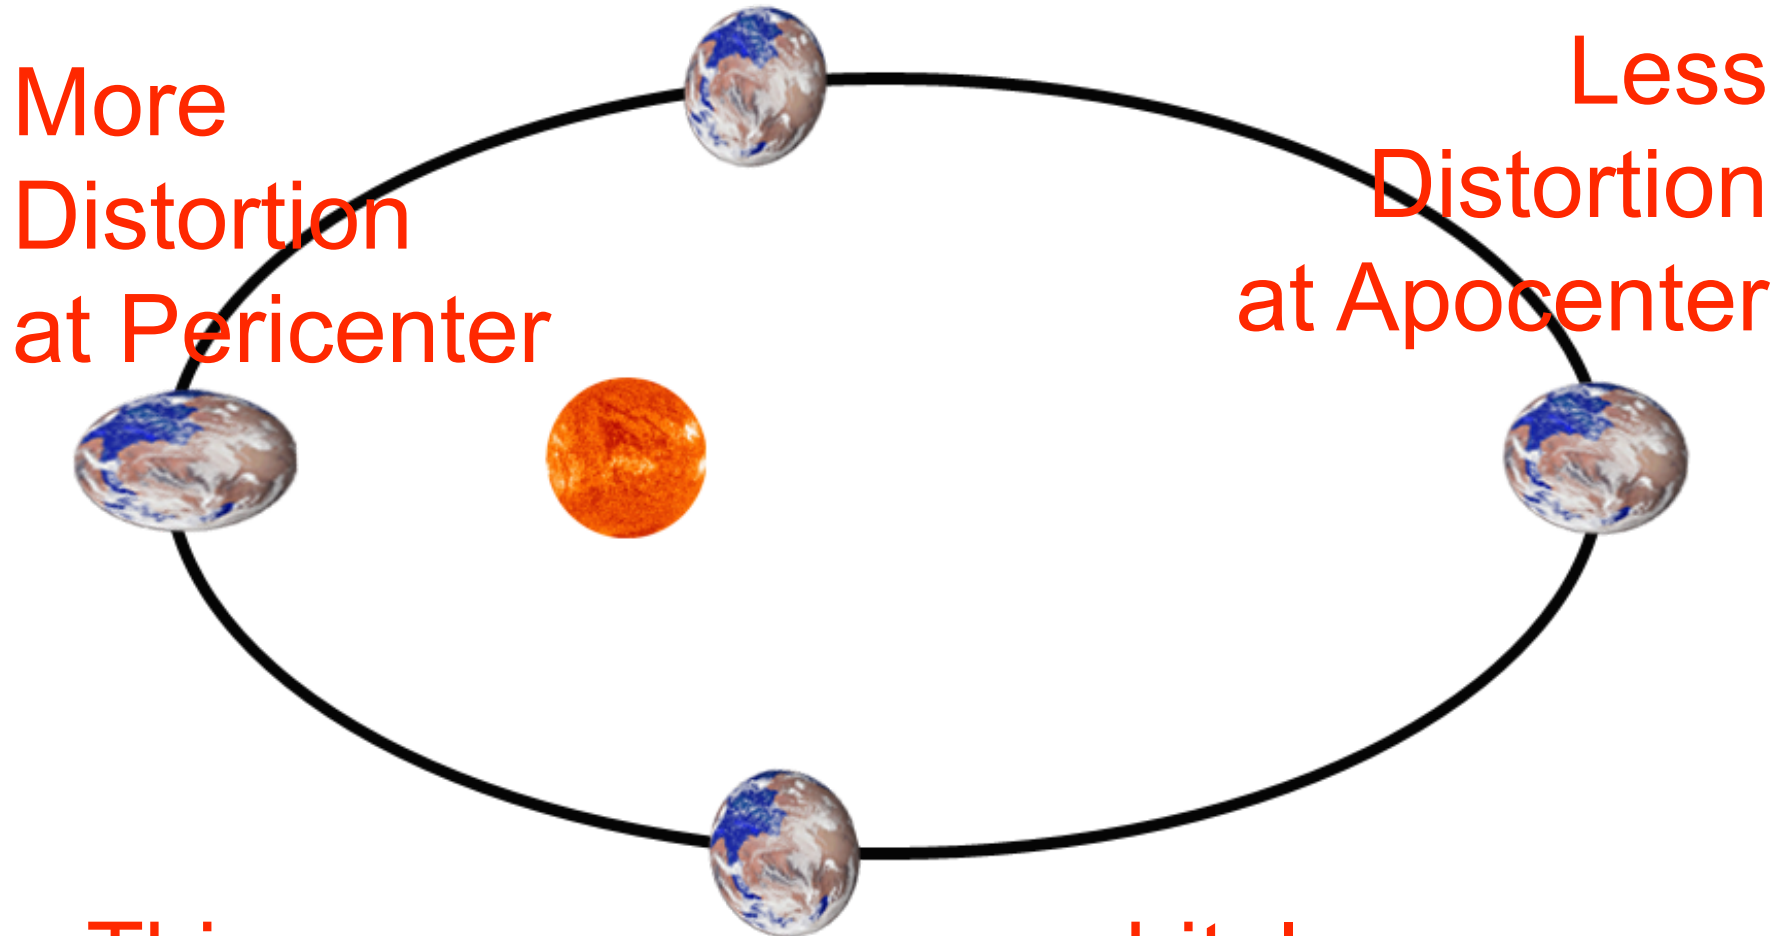

Effect of Eccentricity

Planet changes shape during orbit!

Tidal Heating

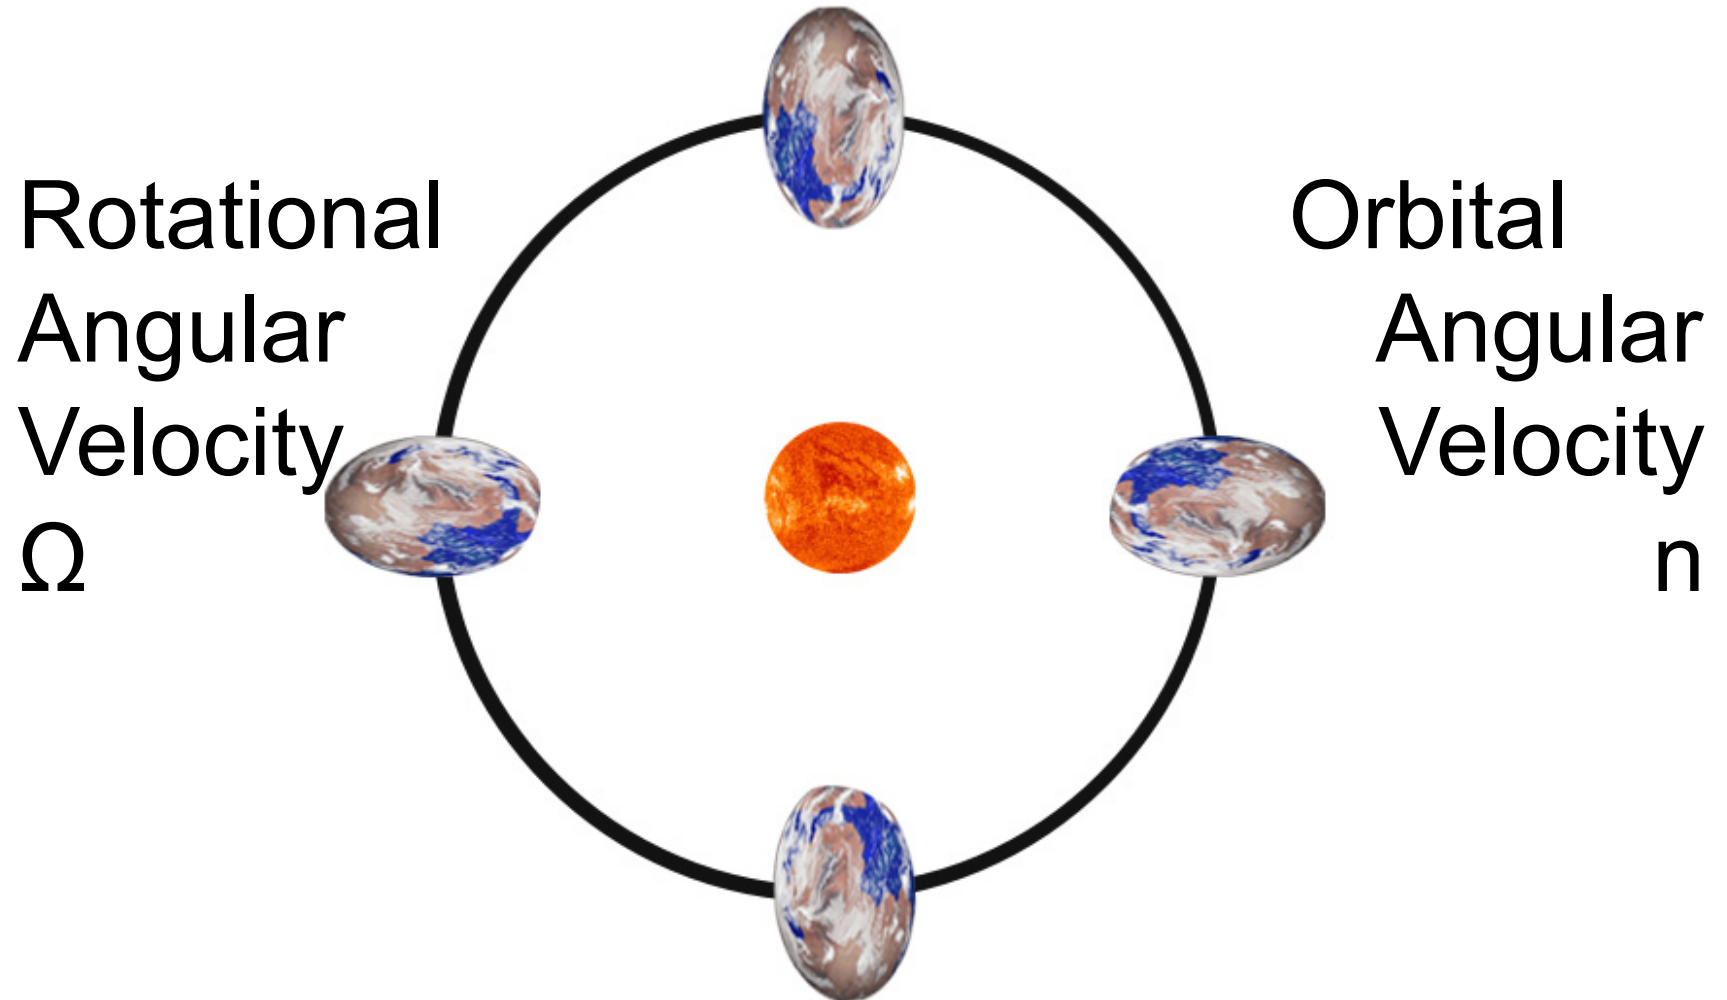

This process removes orbital energy
=> The orbit decays

Rotation is Controlled by Bulge

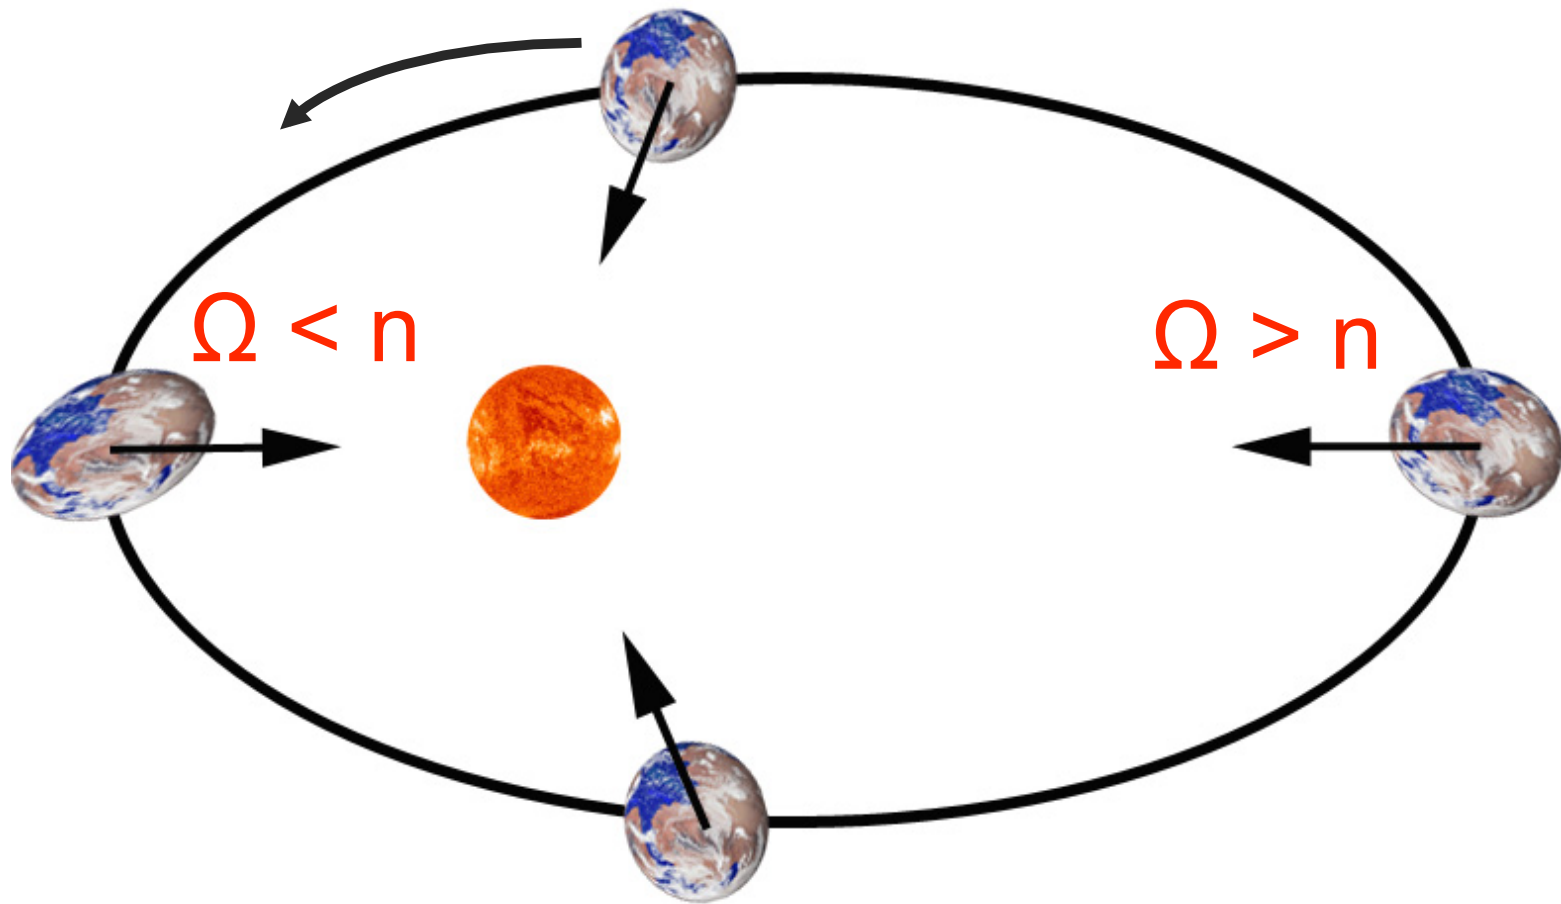

Rotation is Controlled by Bulge

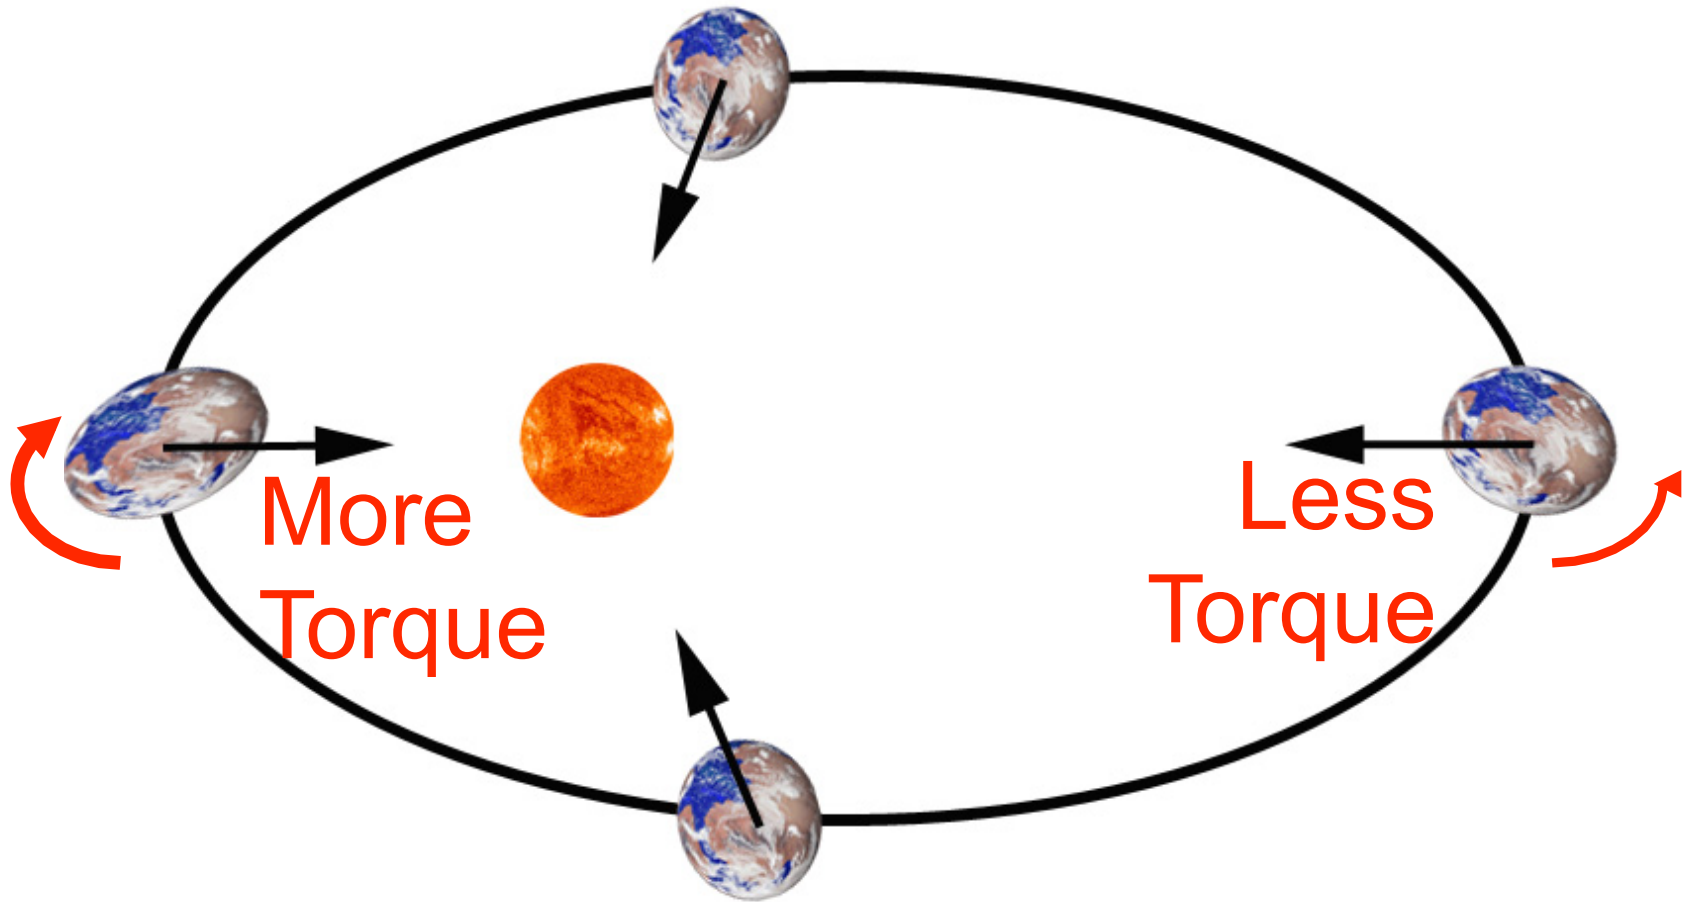

Circular orbit => Synchronous Rotation

Tidal Locking

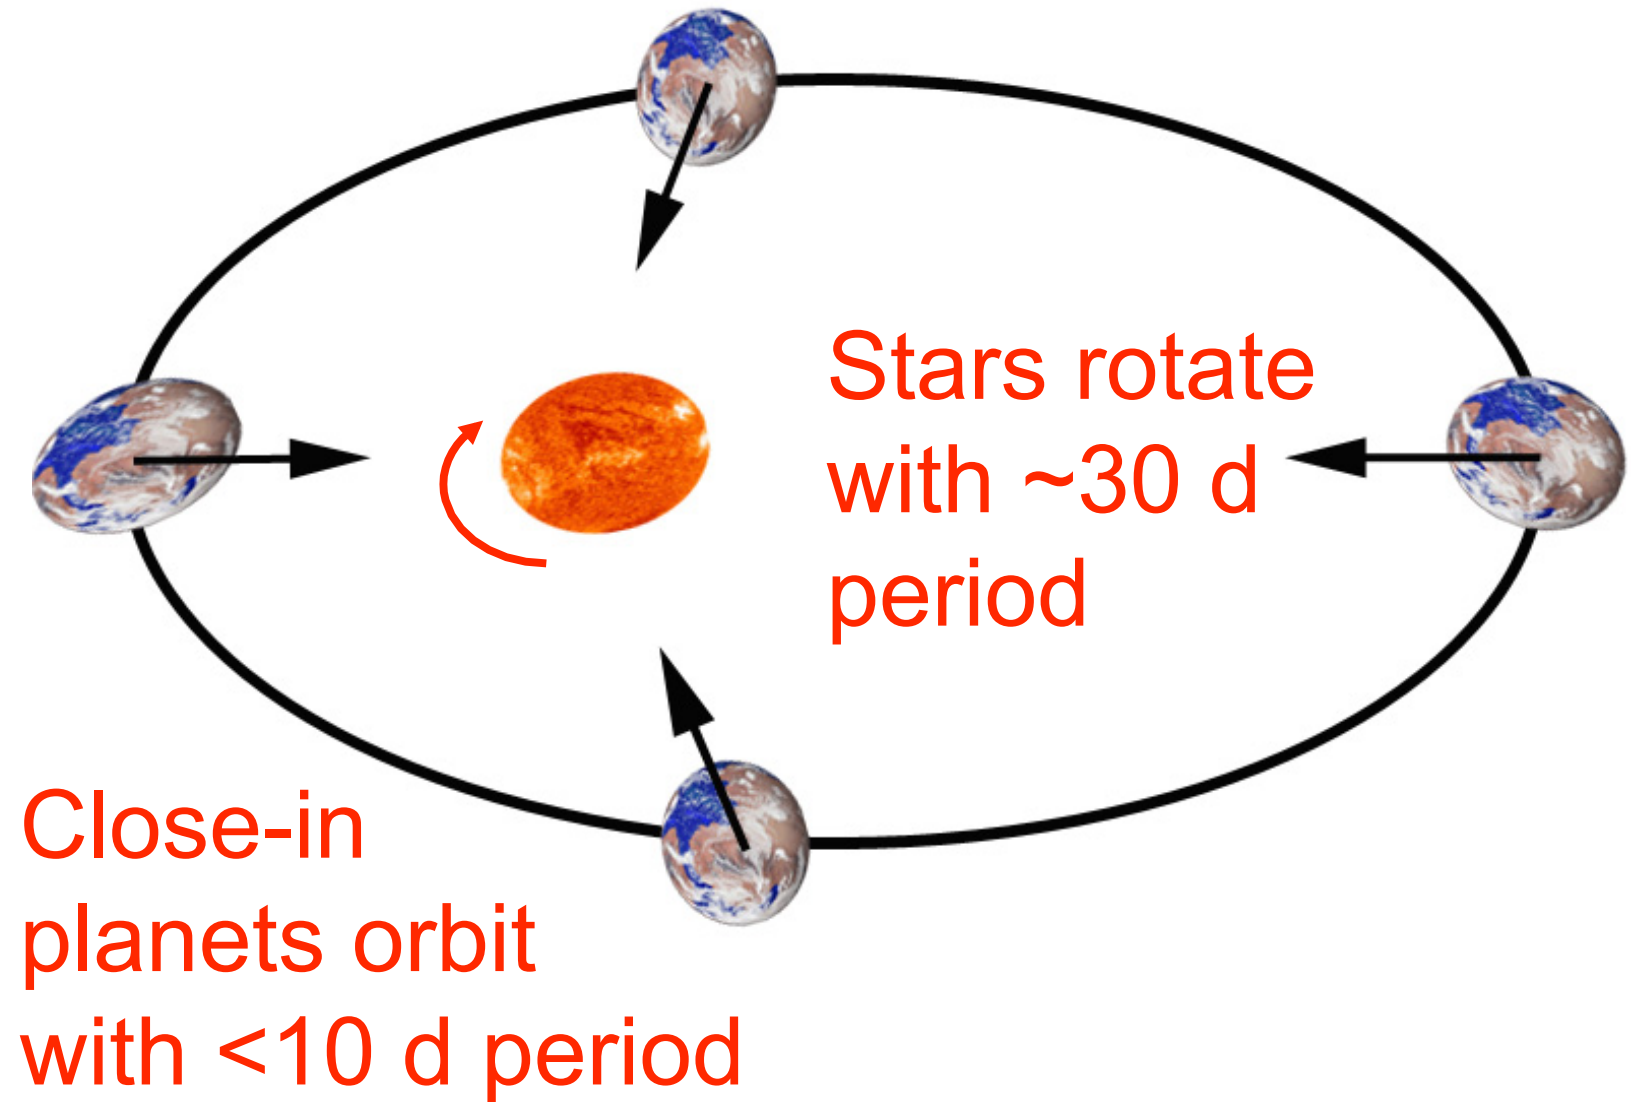

At peri, the planet rotates slower than it orbits
At apo, it rotates faster

Tidal Locking

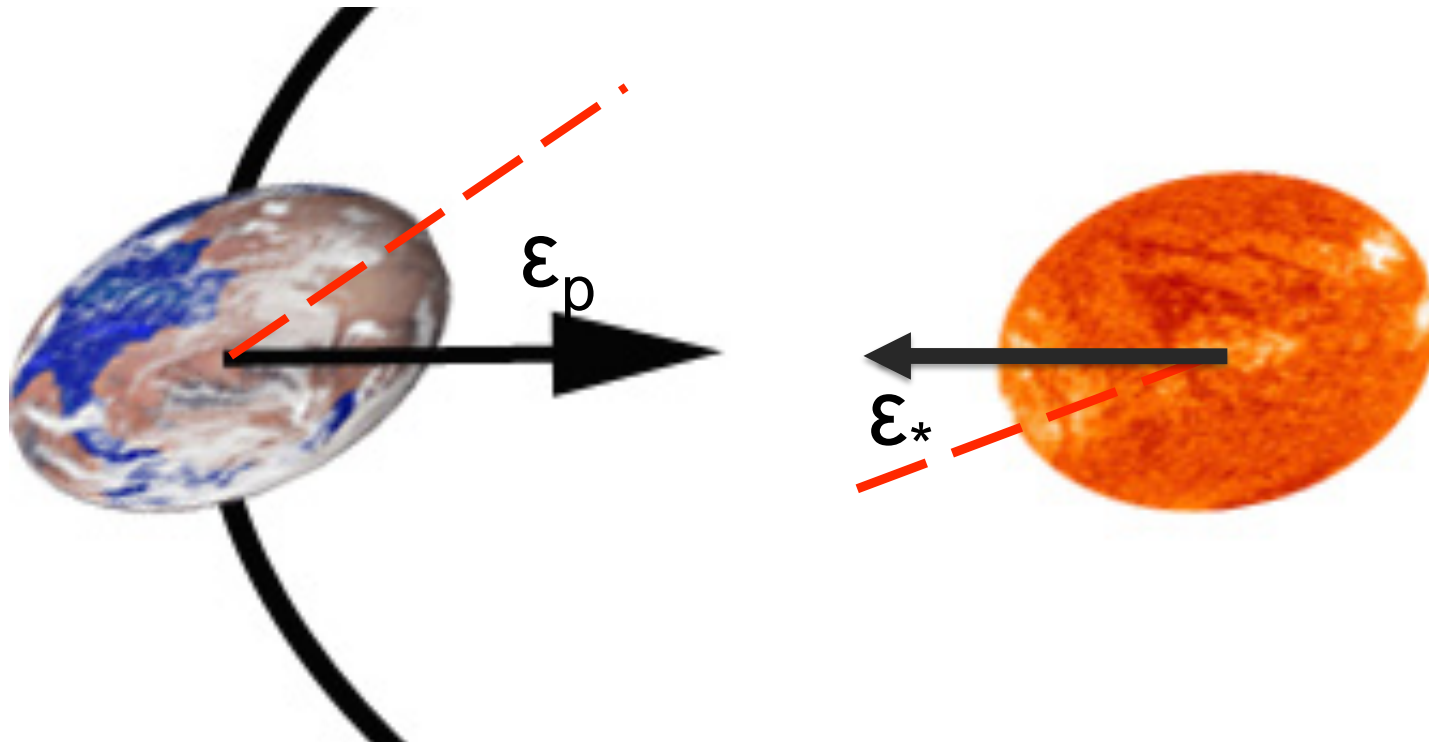

Tidal locking = Rotation controlled by bulge
Rotation is faster than synchronous ($e > 0$)

The Star is Torqued Too

The Magnitude of Tidal Evolution

The bulges lag the perturber by angle ε

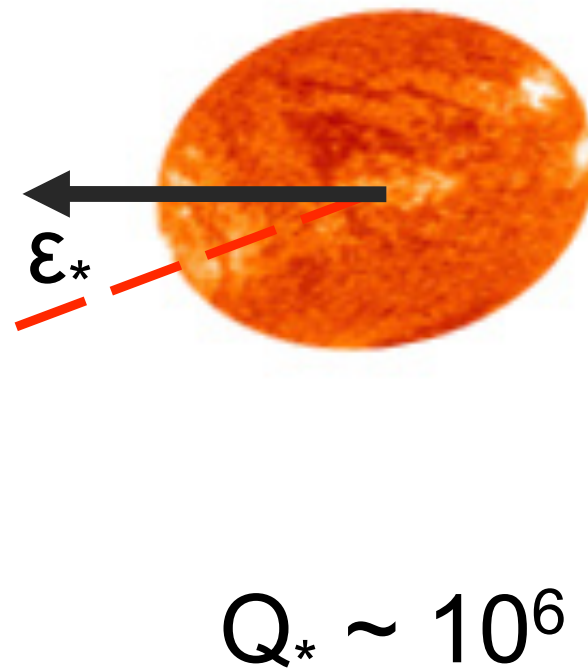

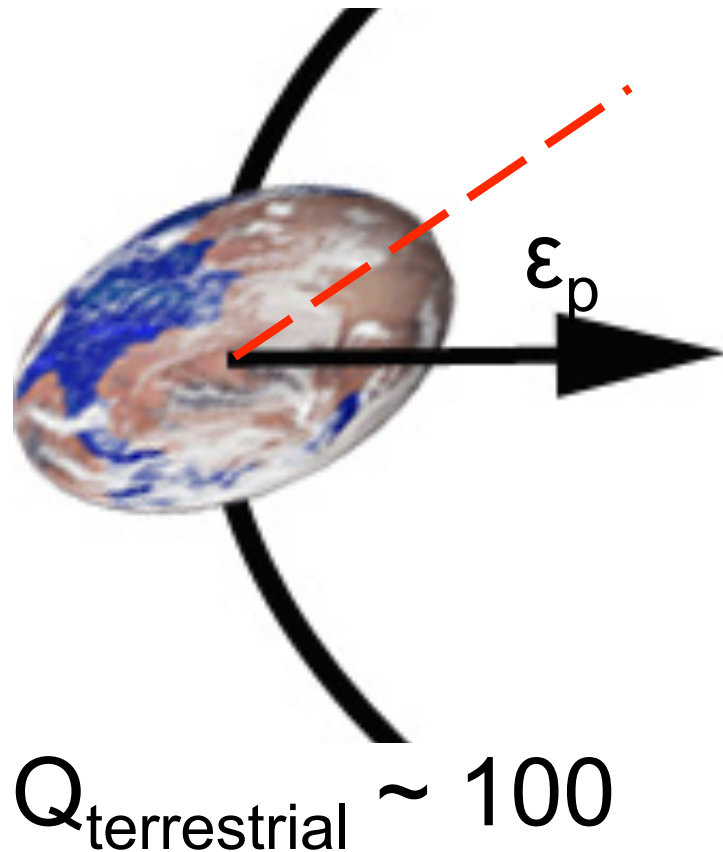

ε depends on internal structure

This is a poor approximation!

The Magnitude of the Tidal Evolution

Usually we talk about “tidal Q” = $1/\epsilon$

Initial Conditions to Tidal Locking

Rotation (rate and tilt) set at last major impact

Obliquities driven to 0 or π

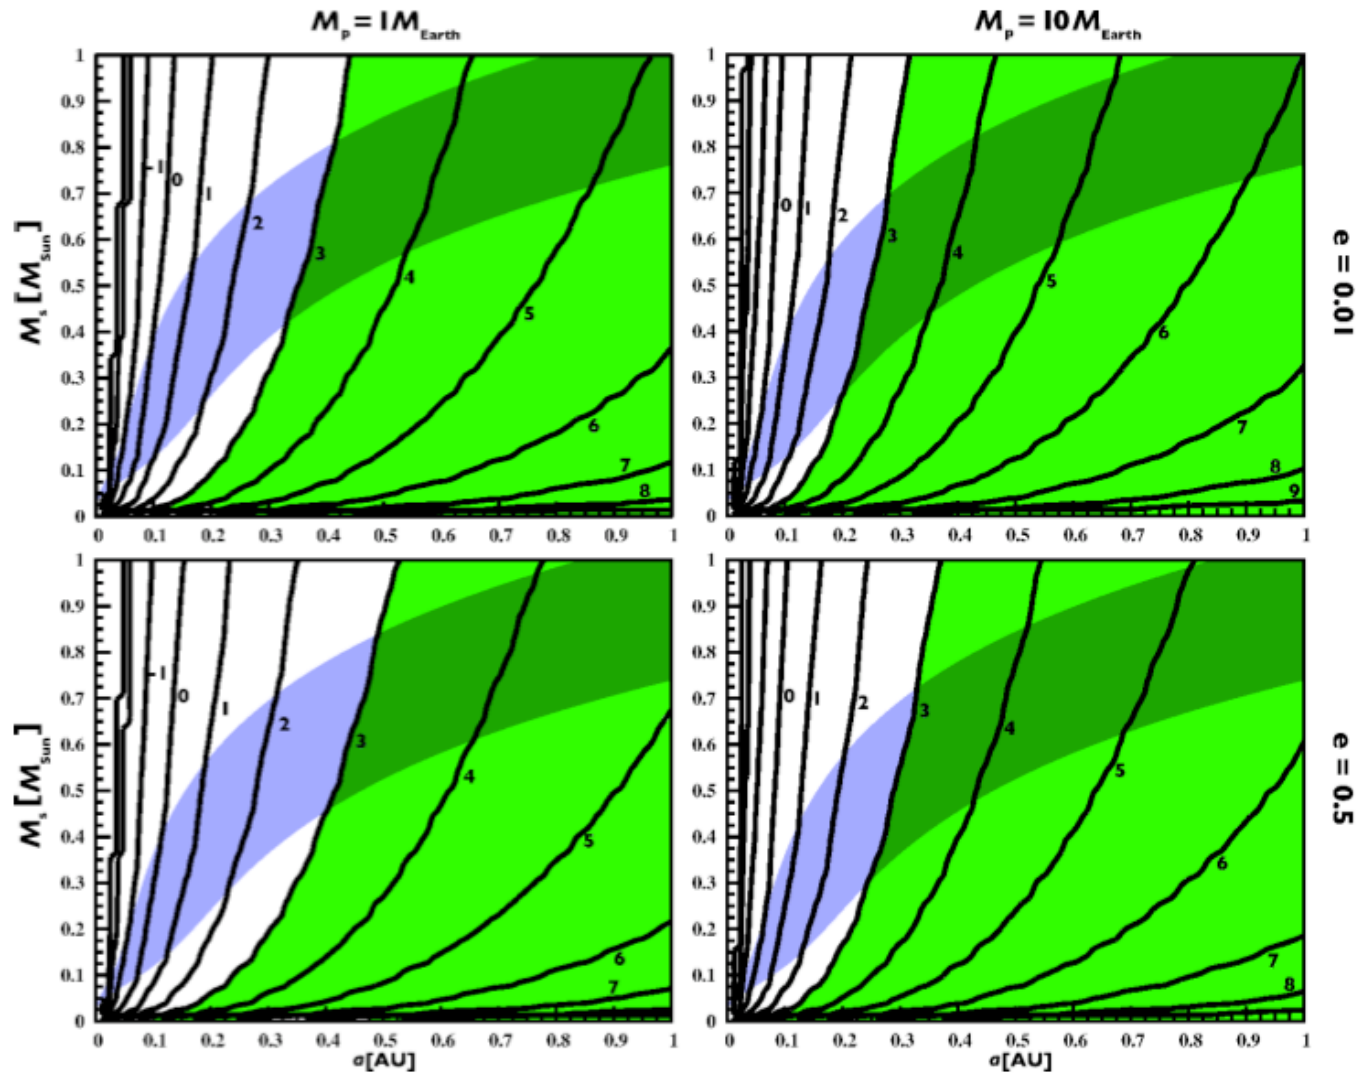

Rotation rate driven to equilibrium
(synchronous if $e=0$)

When these conditions are met, the planet is
“tidally locked” (planetary rotation irrelevant)

Further evolution requires $e \neq 0$, or tides raised
on the star

Oblivities $\rightarrow 0$ (or π)

Time (Gyr) to go from 23.5 to 5 degrees

Equilibrium Rotation Periods ($10 M_E$, $0.25 M_S$)

Orbital Evolution

Energy dissipated $\Rightarrow a$ decreases

Ang. mom. transferred $\Rightarrow e$ decreases

Assume bulge modeled by linear

superposition of spherical harmonics

Assume ε is (in)dependent of frequency

Calculate gravitational forces between
bulges

Transform into orbital elements to obtain
rates of change of a and e

Tidal Evolution

Energy dissipated $\Rightarrow a$ decreases

Ang. mom. transferred $\Rightarrow e$ decreases

Lots of dubious assumptions
&
Lots of math

$$\frac{da}{dt} = - \left(\frac{63}{2} \frac{\sqrt{GM_*^3} R_p^5}{m_p Q'_p} e^2 + \frac{9}{2} \frac{\sqrt{G/M_*} R_*^5 m_p}{Q'_*} \left[1 + \frac{57}{4} e^2 \right] \right) a^{-11/2}$$

$$\frac{de}{dt} = - \left(\frac{63}{4} \frac{\sqrt{GM_*^3} R_p^5}{m_p Q'_p} + \frac{225}{16} \frac{\sqrt{G/M_*} R_*^5 m_p}{Q'_*} \right) a^{-13/2} e$$

Barnes *et al.* (2009)

Barnes *et al.* (2009)

Summary

Planets close to their star have their shapes distorted by tides

Evolution driven by misalignment between bulge and perturber

Tides initially drive rotation rate toward orbital period and obliquity to zero or π

After tidal locking, orbits may continue to evolve: a and e decay

Planets may exit the HZ due to tides

Planets may merge with their star

Tidal heating accompanies eccentric orbits
Super-Ios, Tidal HZ
